

Oil Path Prediction and Optimization for High Speed Transmissions with ParticleWorks

EASY

The word "EASY" is rendered in a large, bold, blue sans-serif font. The letter "Y" is the focal point, with a white dot at its base from which numerous thin, light-blue lines radiate outwards, resembling a particle simulation or a network diagram. The background features faint, light-blue circular and linear patterns, suggesting a technical or scientific context.

CASE STUDY

ELECTRIC MOTOR

COUPLING GEARBOX

AXLE

Application: WHEEL LOADER

TARGETS

- Proper lubrication in each working position and for each input speed
- Oil level optimization to minimize power losses

COUPLING GEARBOX DATA

- Overall ratio: 11,43
- Input speed: 700 - 6000 rpm
- Both cw and ccw sense of rotation
- 0° - 30° - 60° - 90° working positions

MODEL BUILDING

HOUSING
INNER
SURFACES

OIL DATA

- $T = 40^{\circ}\text{C}$
- $\rho = 875 \text{ kg/m}^3$
- $\nu = 6,00 \text{ e-}5 \text{ m}^2/\text{s}$
60 cSt
- $\gamma = 0,03 \text{ N/m}$
- Oil qty = 1,00 l

WORKING POSITION 30° TO VERTICAL

Case Studies	1	2	3	4	5	6
Input speed [rpm]	705	705	2500	2500	6000	6000
Sense of rotation	CW	CCW	CW	CCW	CW	CCW

MODEL SETUP

	Simulation Parameters	Simulated values
1	Courant Number	0,20
2	Speed of Sound [m/s]**	8
3	Turbulence	ON
4	Slip Factor	5
5	Particle Size [mm]	0,70
6	Pressure Smoothing	OFF
7	Surface Tension Model	Potential

**calculated as 5*Tangential Speed max @ 705 rpm, applied at each speed

... SOME DATA ABOUT SIMULATION RUNS:

- 3.000.000 Particles
- Time steps from 8,5 E-05 to 1,0 E-05
- Simulation time : 2 simulation sec / 1 day on average
- Running on a NVIDIA K80 Graphic Card 12 GB GRAM

Sensitiveness to the parameters 4, 5, 6 and 7 has been done to understand how they affect the oil path and, thus, to choose the best setup for the model

MODEL SENSITIVENESS

Slip factor 1

Slip factor 5

MODEL SENSITIVENESS

Particle size 0,7 mm

Particle size 1,0 mm

MODEL SENSITIVENESS

Pressure smoothing: OFF
Surface tension model:
Potential

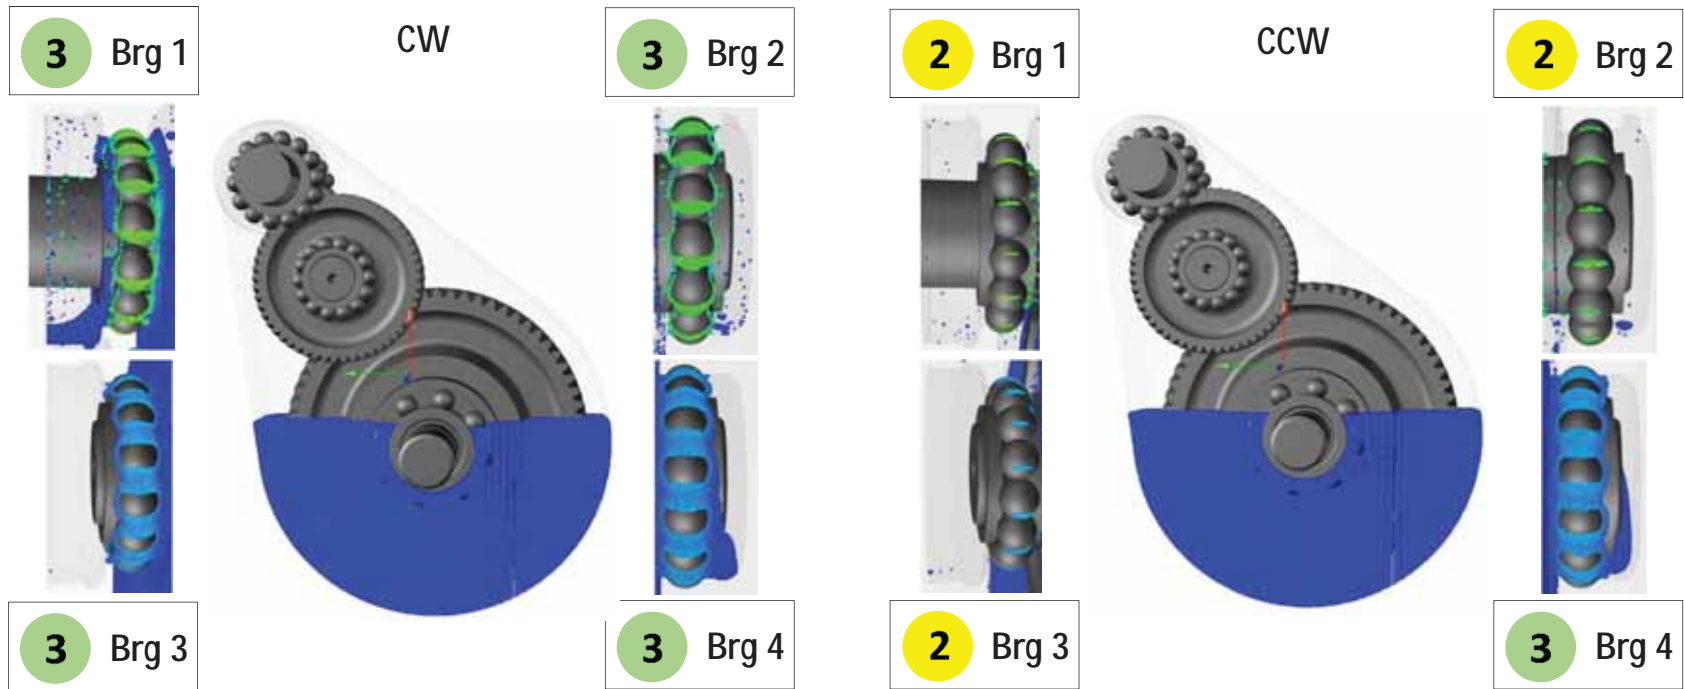

Pressure smoothing: ON
Surface tension model: CSF

RESULTS

SIMULATIONS

BEARINGS LUBRICATION LEVELS

TESTS

*with foam

*with foam

Single particles between rollers, no accumulation

Only few drops out of the bearing during the rotation

Groups of few particles between rollers, no accumulation

Thin film during rotation or while the gearbox is stopping

Good accumulation between rollers and beyond the brg

Thick film during the rotation, accumulation beyond the brg

Huge accumulation between rollers and beyond the brg

Huge accumulation beyond the brg during the rotation

CONCLUSIONS

- A gearbox for high speed applications has been simulated to verify the proper lubrication of all the components
- Simulations have been done considering three input speed levels: 705 rpm, 2500 rpm, 6000 rpm and both the rotation direction, clockwise and counterclockwise
- While in the CW direction, the lubrication is properly distributed on all the bearings, in the CCW direction is poorer
- In the CCW direction, furthermore, the minimum oil quantity in the upper bearings is reached at an intermediate speed, while the oil quantity is greater at low and high speed
- A comparison with physical tests has been done: very good compliance between simulations and tests has been done both in terms of oil path description and oil quantity in the bearings. A slight difference has been detected at 6000 rpm, when the oil flow becomes foam.
- The compliance between simulations and tests has allowed to establish a qualitative scale of values for judging the lubrication levels tuned with the test scale
- Next steps: simulations with different housing geometry to guarantee lubrication with the same oil quantity
- Next steps: implementation of the air in the model in order to model the foam
